INTRODUCTION

This annual district report describes the status of insect and disease conditions in the 12 forest districts (Fig. 1) and in urban areas of the Province. A total of 815 insect and 91 disease collections were processed by the Forest Insect and Disease Survey. Twelve new insect species were identified in these samples. An additional 943 samples were collected during the spruce budworm egg-mass survey and 285 during the hibernacula survey.

Aerial surveys of the Island and Labrador were conducted in September and approximately 50 hours were flown in fixed-wing aircraft and 150 hours in helicopter, for the spruce budworm egg-mass survey and on damage assessment surveys. The Forest Protection Division of the Provincial Department of Forestry and Agriculture provided most of the aircraft time and assisted in the spruce budworm egg-mass sampling and counting. Personnel from the National and Historic Parks Branch of the Department of Indian Affairs and Northern Development collected spruce budworm egg-mass samples in the Terra Nova and Gros Morne National Parks.

In 1977 forest insect and disease survey personnel also established 10 permanent sample plots for monitoring insect and disease conditions; lectured forestry students of the College of Trades and Technology and a group of conservation students from across Canada on insect and disease conditions in the Province; assisted the Department of Forestry and Agriculture, Forest Protection Division, by providing a plan for monitoring the spruce budworm and instructing field crews in sampling methods and supervising students in insect counting for an experimental spruce budworm chemical control program; collected Elateridae spp. (click beetles) as a contribution to the pilot project of the biological survey of the insects of Canada; collected tussock moth eggs for research studies by Dr. J.C. Cunningham of the Insect Pathology

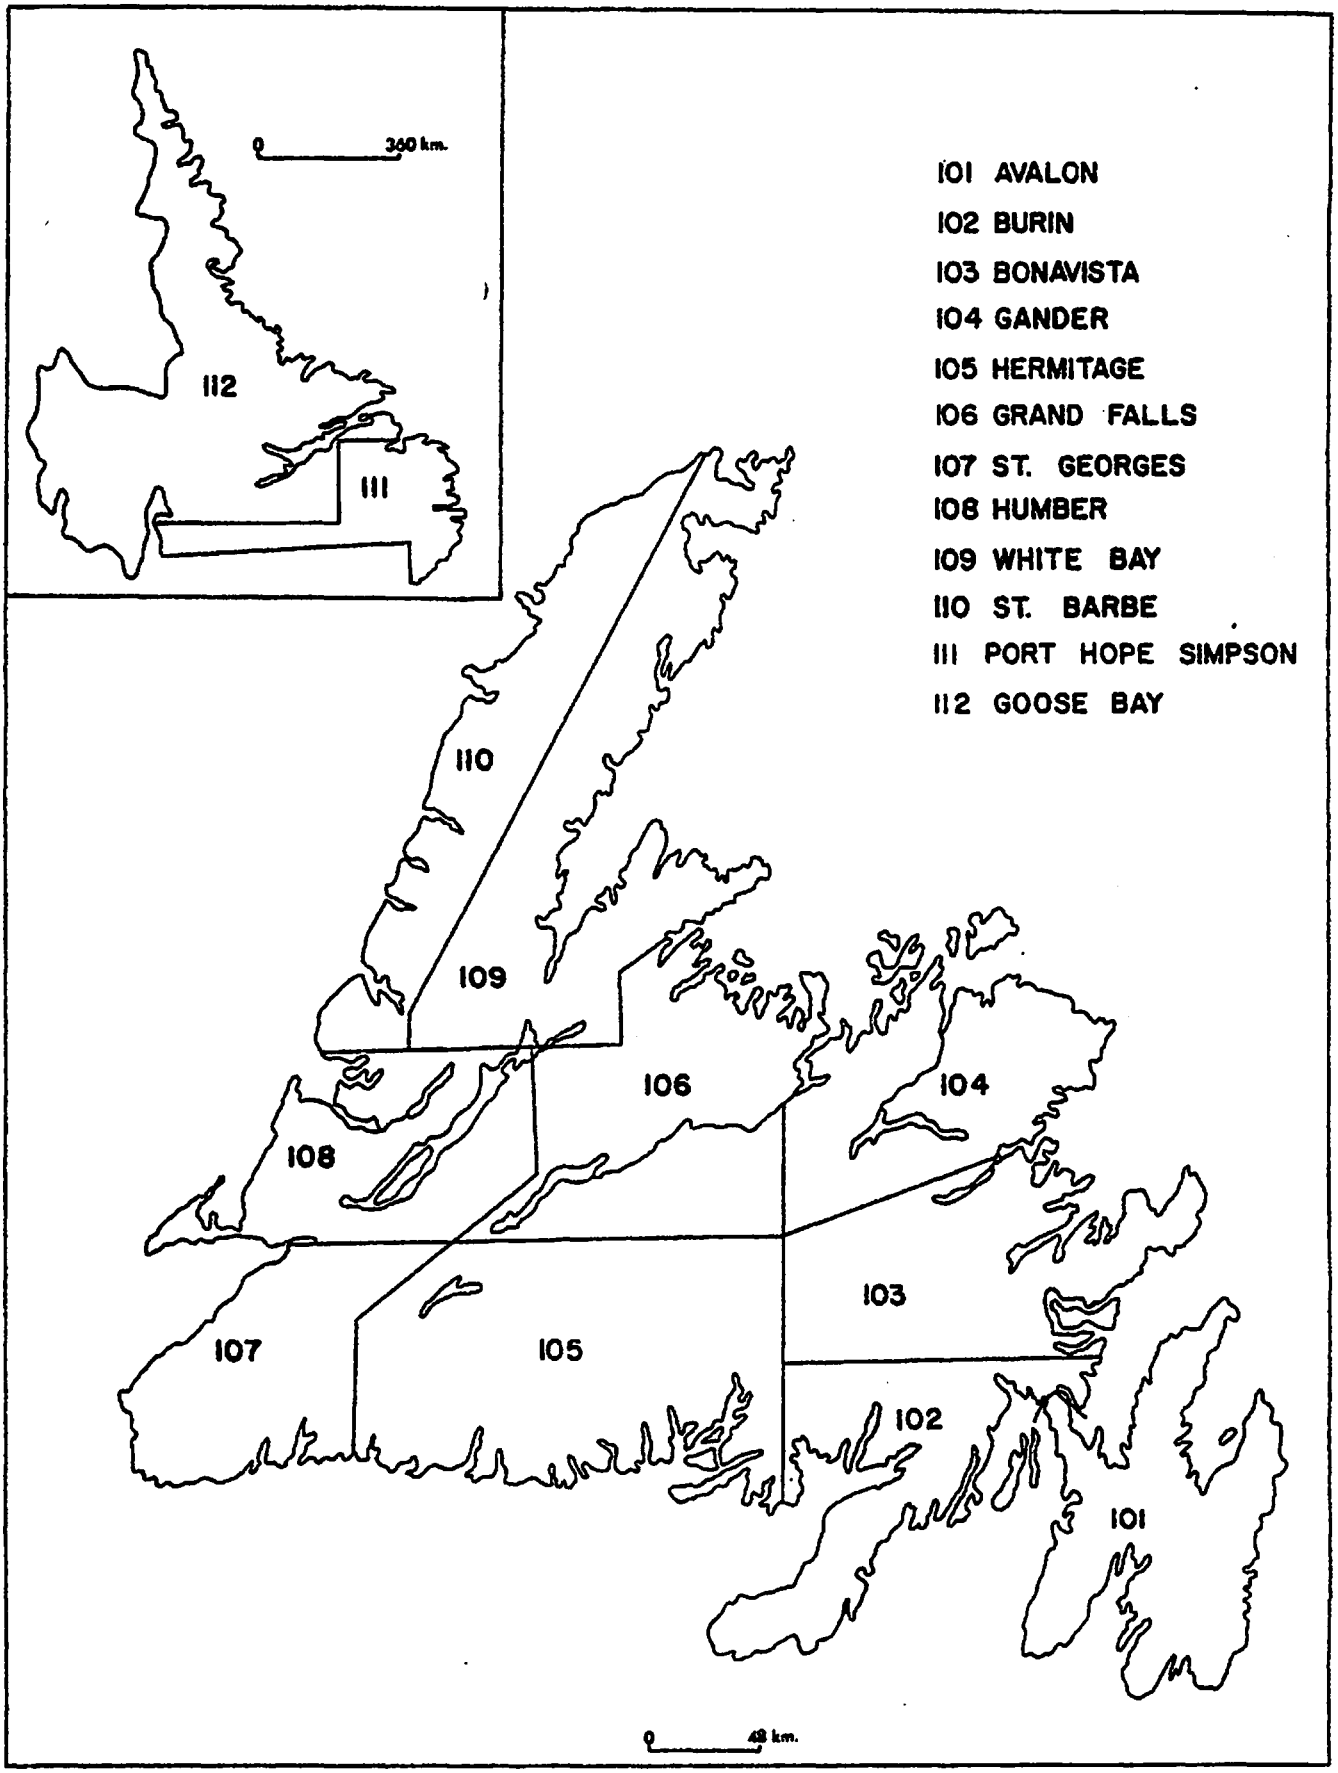

Fig. 1. Forest Insect and Disease Survey Districts.

Research Institute, Sault Ste Marie; conducted a five-day trapping program to monitor population levels of the masked shrew; advised municipal councils and property owners on identification and control of insects and diseases on ornamental trees and attended an Area Development conference on forestry problems in Baie D'Espoir.

From May to early July, cool wet weather accompanied by high winds prevailed throughout western and part of central Newfoundland setting a new precipitation record for western Newfoundland. Warm, dry conditions occurred throughout eastern Newfoundland. Labrador weather was cool, and wet throughout the summer with patches of snow visible all summer in the Cartwright area and numerous icebergs visible along the coast. Temperatures and precipitation for the past seven years are shown in Table 1.

The spruce budworm continued to be the major insect pest in the Province for the sixth consecutive year. The blackheaded budworm populations showed a sharp decline in eastern Newfoundland, on the Northern Peninsula and in Labrador. The eastern hemlock looper continued to increase on the Island especially in areas where spruce budworm populations had decreased. Balsam fir sawfly population levels collapsed in Labrador and remained low on the Island. There was no appreciable change in the balsam woolly aphid population levels and larch casebearer were reported in outbreak numbers in the Terra Nova National Park and in the St. John's area. The larch sawfly populations were lower than 1976 but severe defoliation occurred throughout the outbreak area. The birch casebearer outbreak was the most widespread and severe ever recorded on the Island. Other hardwood defoliators such as the large aspen tortrix, poplar leaf roller, ugly nest caterpillar, satin moth, tussock moth, mountain ash sawfly and the fall webworm were collected in high numbers in localized infestations.

Broom rusts of balsam fir and spruce continued to be the most conspicuous disease of forests on the Island. Dothichiza canker of lombardy poplar continued to be the most important disease in residential areas on the Island. A moderate to severe infection of ink spot of trembling aspen continued in the Goose Bay area.

Frost damage of balsam fir regeneration in logged over areas was widespread and extensive throughout the Island. Other common tree diseases such as shoot and leaf blight of aspen, needle rusts, leafspots and rust galls were generally low and caused minor damage.

IMPORTANT FOREST INSECTS

Spruce Budworm, Choristoneura fumiferana (Clem.) — In 1977 larval activity commenced one to two weeks later than usual and defoliation was not observed until late June. The outbreak covered virtually all of the forest areas on the Island. In western Newfoundland from Robinsons River to Georges Lake, larval populations were high (up to 500 per tree sample) and tree defoliation severe. However, from Georges Lake to Bonne Bay and south of the Trans Canada Highway to Badger, larval populations were considerably lower (up to 85 per tree sample) and defoliation, although widespread and severe, was not as extreme as 1976 (Table 2). The probable reasons for the decline in larval populations in this area were unfavourable weather conditions and starvation. Severe defoliation and high population levels were also recorded north of the Trans Canada Highway from White Bay east to St. John's, throughout the Bonavista and Avalon peninsulas, from Badger south to Baie D'Espoir and in isolated spots near Red Indian Lake and from Roddickton to Ten Mile Lake (Figs. 2, 3, 4 and 5). Another observation was the high numbers of budworm that overwinter on larch and cause complete defoliation in early summer. There was considerable defoliation of larch in many areas of central and eastern Newfoundland in 1977 particularly on Random Island and throughout the Terra Nova National Park. However, by late August virtually all of the larch in these areas had refoliated.

Damage Assessment

The annual aerial defoliation survey scheduled for early August was cancelled because heavy rains and high winds washed off the damaged and reddened foliage making it impossible to record tree defoliation from the air. However, a special aerial damage assessment survey, augmented with ground checks, was conducted in late August to determine the areas and merchantable volume of dead and damaged stands. This survey classified the merchantable forests of the Island into four major categories, A - dead standing; B - moribund, severely damaged and not likely to survive; C - severely damaged but should recover; and D - very light or no damage. All watersheds and other forested areas were surveyed from a fixed-wing aircraft. The survey showed 275 areas classed as A and B. Approximately 100 ground checks were made in these areas by helicopter to check the aerial classification and to estimate wood volume. The area of merchantable stands classified as dead was 64 013 ha containing an estimated 5 137 705 m^3 of wood. The area of moribund stands totalled about 110 519 ha with approximately 8 507 165 m^3 of wood (Table 3). Mature stands severely damaged but likely to survive totalled 773 738 ha.

Damage assessments were also conducted in stands of balsam fir regeneration. Cruise lines were run in 22 areas and consisted of 200-400 metres per line with a one to 4 m^2 plot 20 to 40 m apart, depending on the density of the stands. Results of these surveys showed that the area of severely damaged stands was about 692 491 ha and the area of very severely damaged stands containing some mortality was about 20 313 ha. Tree mortality was low, less than 10% but it was as high as 28% in one plot of larger trees in the Trout Brook area. Stands in this area were severely damaged by the balsam fir sawfly prior to the budworm outbreak. Defoliation by the spruce budworm in stands of regeneration also retarded height growth of balsam fir, most of this height loss resulted from top-killing. Approximately, one to six years height growth have been lost depending on the extent of top-killing in these stands.

A map showing the intensity of defoliation on the Island was also prepared from 923 ground checks made during the egg-mass survey. The areas of productive forests classed into light, moderate and severe defoliation categories are shown in Table 4. The total area of defoliation was about 2 700 000 ha.

In Labrador, the outbreak covered an area of 52 678 ha of mature balsam fir-black spruce forest of which 31 796 ha were in the moderate to severe defoliation class and the remaining 20 882 ha were lightly defoliated (Fig. 6). The volume of dead trees scattered within the severely damaged area was about 236 384 m^3 and an additional 531 867 m^3 were classed as moribund (Table 3).

In 1977 larval and pupal parasitism increased to 35% and reached a high of 80% in some of the older infested areas of western Newfoundland. Parasitism in the late larval and pupal stages probably would have been higher had it not been for the fungal disease, caused by Entomophthora spp., which became widespread in late summer. This disease caused about 30% mortality in late larval and pupal stages and as high as 60% in some locations in western Newfoundland.

Surveys of egg masses and overwintering larvae were conducted at 943 and at 285 locations respectively (Appendices I and II). The results indicate that this insect will continue to be the most important forest pest during 1978. The infestation now covers virtually all of the fir-spruce forest on the Island. Population levels in some areas will be lower than last year but still high enough to cause noticeable damage throughout most of the Island. Severe defoliation will occur in about 1 354 919 ha distributed from the Codroy Valley to the south end of Grand Lake in western Newfoundland and along the northeast coast from White Bay to St. John's and south from Gander to Baie D'Espoir (Fig. 7). This forecast includes an

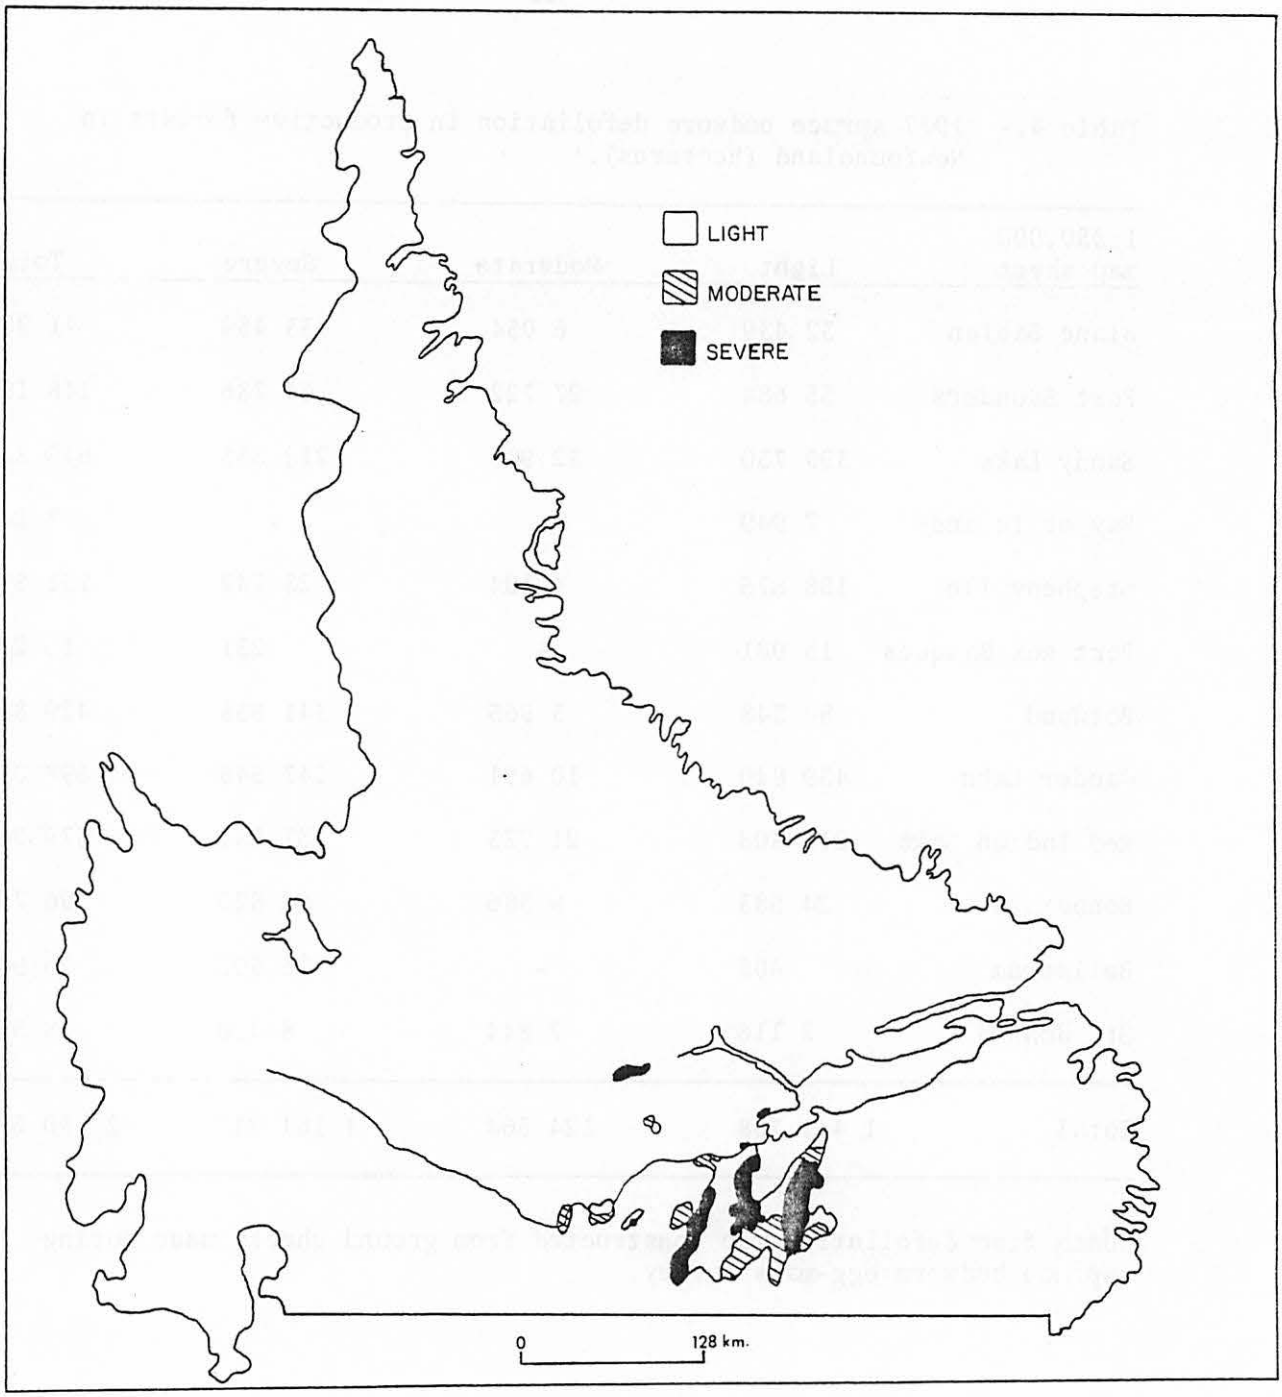

Fig. 6 Spruce budworm defoliation in Labrador - 1977

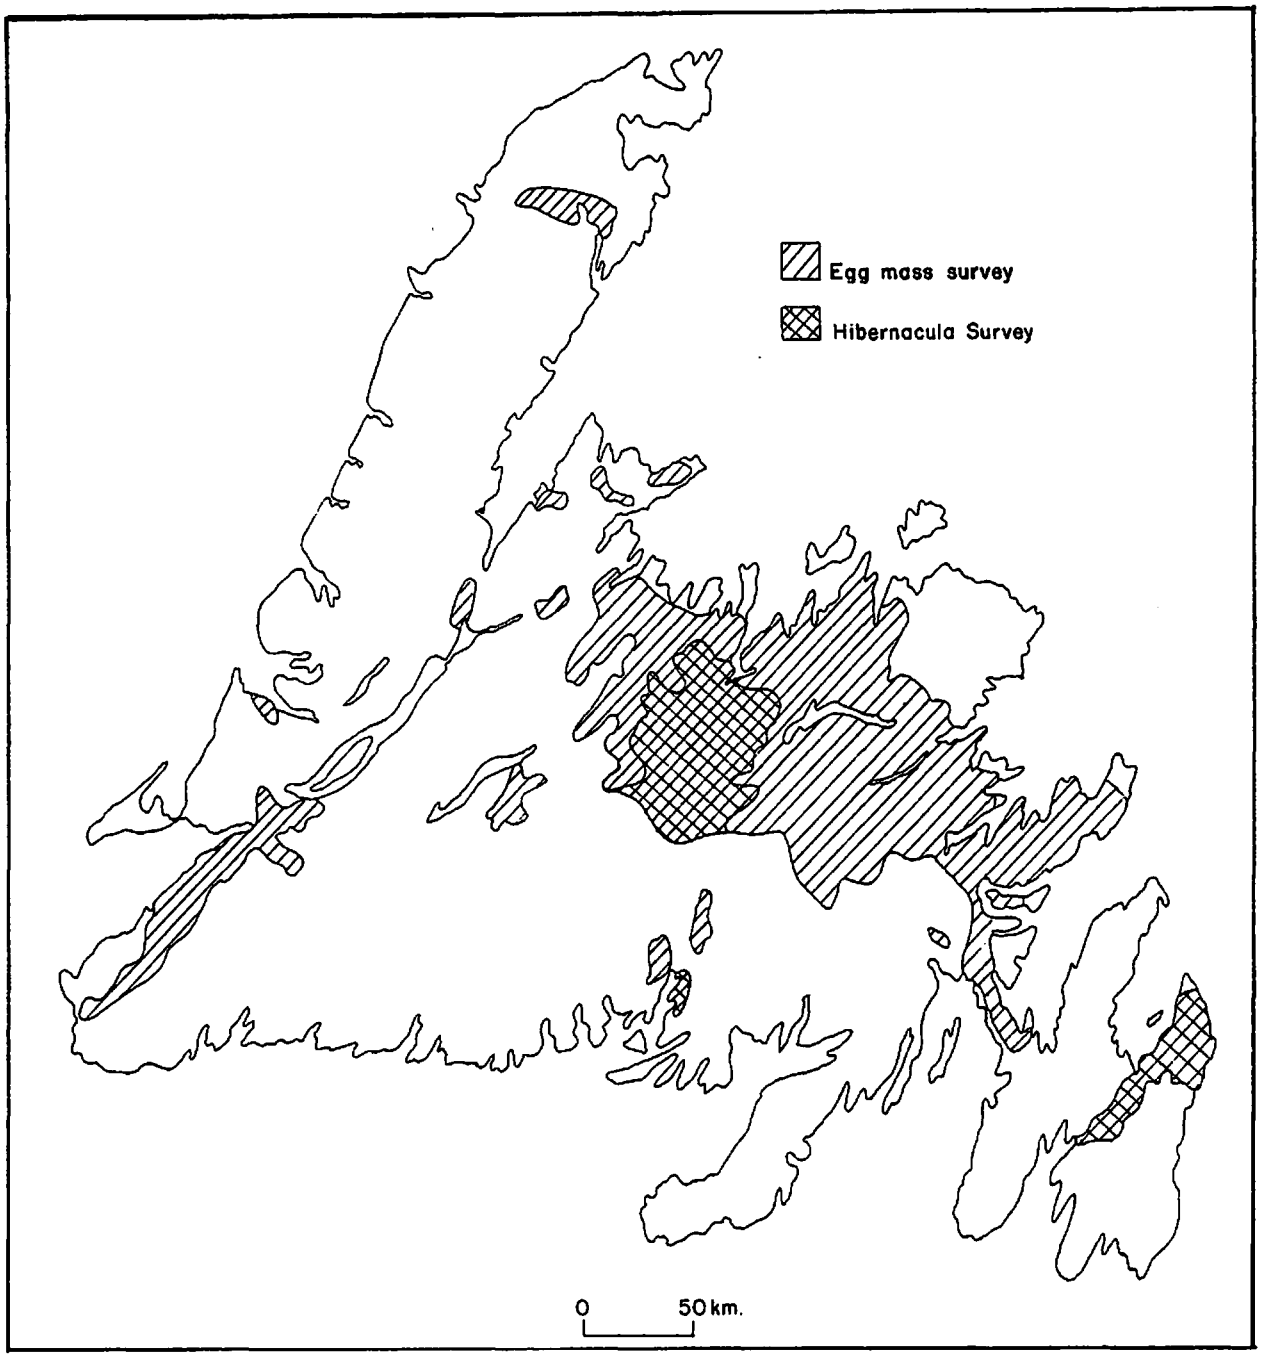

Fig 7. Areas of moderate and severe defoliation predicted for 1978 based on the egg mass survey and the hibernacula survey.

increase of 322 000 ha over predictions based on the egg-mass survey. This increase is attributed to an increase in populations caused by budworm dispersal in some areas, notably the Grand Falls, Gander Lake and Baie D'Espoir areas and the Avalon Peninsula. Tree mortality is forecast to continue in mature stands classified as moribund in 1977 and may increase by 10% particularly in mature stands in western Newfoundland where severe defoliation is predicted and where the budworm has caused severe defoliation for three to four consecutive years. Tree mortality in regeneration and semi-mature stands will occur mainly in western Newfoundland and approximately 50% mortality is expected in stands in the Trout Brook-Harry's River area where 90-100% of the total foliage was destroyed in 1977 and where previous balsam fir sawfly damage occurred. In Labrador the outbreak is expected to remain the same as 1977. The major part of the outbreak and defoliation and tree mortality will be in the mature balsam fir stands in the Kenamu and Traverspine River watersheds and in the Mud Lake area.

Year	No. of collections	No. of larvae per tree sample		
		Min.	Avg.	Max.
1977 - Island	343	0.0	59.4	333.0
1977 - Labrador	17	0.3	28.7	183.3

Eastern Hemlock Looper, Lambdina fiscellaria fiscellaria (Guen.) — Population levels of this insect fluctuated throughout the Province; higher looper counts were found where spruce budworm numbers declined and lower where budworm numbers increased. In eastern Newfoundland the infestation on the Bellevue Peninsula collapsed. Larval numbers were reduced to 7 per tree sample at Whelans Pond and to 11 per tree sample along Cochrane Pond Road. Larval counts from 4 to 7 per tree sample were also collected at Twin Lakes and Lake Ambrose in central Newfoundland and at Goose Arm, Rocky Harbour, Daniels Harbour and South Brook Valley in western Newfoundland.

Year	No. of collections	No. of larvae per tree sample		
		Min.	Avg.	Max.
1977	35	0.1	1.9	25.0
1976	21	0.1	12.9	196.7

Population levels in western Newfoundland are forecast to increase in 1978 especially where spruce budworm numbers will decrease.

Blackheaded Budworm, Acleris variana (Fern.) — The infestations reported in 1976 near Paddys Pond, Terra Nova National Park and Goose Bay collapsed in 1977. Infestations continued in the St. Catherines area where 5-10% defoliation occurred on balsam fir in a 1 375 ha area. Larval counts of 10 per tree sample were collected along the Witless Bay Line but no noticeable

defoliation was observed. Defoliation ranged from 15-90% in mainly balsam fir stands in a 12 000 ha area between Logy Bay and Pouch Cove; in a 3 440 ha area from the Foxtrap access road to Newtown and in a 770 ha area near Bay Bulls Big Pond. Moderate to severe defoliation was also recorded in fir stands from Round Lake to Eddies Cove on the Northern Peninsula although high numbers of the spruce budworm were also collected in this area.

Year	No. of collections	No. of larvae per tree sample		
		Min.	Avg.	Max.
1977 - Island	75	0.0	8.9	85.0
1977 - Labrador	6	0.3	0.7	2.3

Balsam Fir Sawfly, Neodiprion abietis complex — Infestations of this sawfly near Marystown on the Burin Peninsula and along White Bear River and Dove Brook in Labrador collapsed in 1977. Approximately 40% tree mortality occurred on 1 380 ha area along the White Bear River and about 30% mortality on a 465 ha area near Dove Brook. The tree mortality was caused by the combined feeding of the sawfly and the blackheaded budworm.

Year	No. of collections	No. of larvae per tree sample		
		Min.	Avg.	Max.
1977 - Island	5	0.3	0.6	1.3
1977 - Labrador	5	0.3	0.7	1.0

Spruce coneworm, Dioryctria reniculelloides M. & M. — Population levels have increased in 1977 from 4 to 8 larvae per tree sample and collections were made from white spruce, black spruce and balsam fir throughout the Island and Labrador. Damage and defoliation was undetermined because of the concurrent severe damage caused by the spruce budworm.

Year	No. of collections	No. of larvae per tree sample		
		Min.	Avg.	Max.
1977 - Island	56	0.1	8.4	217.7
1976 - "	77	0.3	3.7	27.3
1977 - Labrador	1	1.5	1.5	1.5
1976 "	2	0.3	0.3	0.3

Balsam Woolly Aphid, Adelges piceae (Ratz.) — There was no appreciable change in the distribution or in the intensity of damage in 1977. Infestations reported on Random Island, Bunyans Cove and Swift Current in eastern Newfoundland and Norris Arm-Notre Dame Junction in central Newfoundland remained light and small. No report of new damage was recorded in western Newfoundland.

Larch Sawfly, Pristiphora erichsonii (Htg.) — Population levels of this sawfly increased throughout the Island but caused only light defoliation of tamarack stands. New infestations occurred at Deer Lake, Goose Arm, North Lake, Lomond River and River of Ponds in western Newfoundland. Light defoliation was also recorded in the infestation between St. Georges and South Branch. In Labrador population levels were lower than the 700 per tree sample recorded in 1976. However, defoliation was estimated to be severe and averaged 80-90% in the infested area between Sandwich Bay and Winokapau Lake.

Year	No. of collections	No. of larvae per tree sample		
		Min.	Avg.	Max.
1977 - Island	8	8.0	23.2	50.0
1977 - Labrador	4	8.3	18.4	60.0

Larch Casebearer, Coleophora laricella (Hbn.) — In 1977 population levels increased in eastern Newfoundland and caused severe browning of stands of tamarack in the Terra Nova National Park at Park Headquarters, Saltons Brook and Sandy Pond Junction. Severe browning also occurred on the Avalon Peninsula along the Logy Bay Road, Thorburn Road, Cochrane Pond and Newtown near St. John's.

Parasitism in the Terra Nova National Park infestations was low with only 4 parasites recovered from 134 casebearer larvae. However, in the infestation near St. John's an introduced parasite Agathis pumila (Ratz.) increased from 12% in 1976 to 19% in 1977 (Table 5).

Larch Needleworm, Zeiraphera improbana (Wlk.) — The needleworm infestation in the Newtown-Mount Pearl area continued for the third consecutive year. Severe defoliation, as high as 90%, was recorded on scattered trees and larval numbers averaged about 200 per tree sample.

Year	No. of collections	No. of larvae per tree sample		
		Min	Avg.	Max.
1977	6	0.3	31.1	230.0

Table 5.- 1977 larch casebearer counts

Location	Stand vigour	Stand defoliation	Avg. no. of cases per branch sample

U = unthrifty
M = moderately vigorous
V = vigorous

Stand defoliation:

T = trace
M = moderate
S = severe

European Pine Sawfly, Neodiprion sertifier (Geoff.) — High population levels of this accidentally introduced sawfly caused varying degrees of damage to ornamental pines in the St. John's area. Approximately 1100 pupal parasites, Pleolophus basizonus Crav. were introduced from Ontario and released in a pine plantation near Windsor Lake. Specimens of this parasite were collected in the fall from soil samples from the release area.

Year	No. of collections	No. of larvae per tree sample		
		Min.	Avg.	Max.
1977	2	30.0	40.0	50.0

Rusty Tussock Moth, Orgyia antiqua (L.) — Population levels increased throughout the Island. In eastern Newfoundland small infestations were recorded at Bread Cove Brook and Dunphy's Pond Road areas of the Terra Nova National Park and between St. Phillips and Bauline areas on the Avalon Peninsula. The highest larval numbers, 27 per tree sample, were recorded at Bread Cove Brook. In western Newfoundland larvae were collected throughout the Baie Verte Peninsula. An average of 16.7 larvae per tree sample occurred at the junction of Seal Cove and Wild Cove roads.

Defoliation of roadside trees and shrubs throughout the Peninsula was estimated at 10% near the Seal Cove-Wild Cove Junction and 75-100% along the LaScie and Nippers Harbour roads.

Year	No. of collections	No. of larvae per tree sample		
		Min.	Avg.	Max.
1977 - Island	10	0.3	6.5	50.0

Birch Casebearer, Coleophora fuscedinella (Zell.) — During 1977, population levels of the casebearer increased and the outbreak was the most widespread and severe ever recorded on the Island. The outbreak extended from Port aux Basques to Cow Head and east to Trinity Bay. No appreciable damage was recorded on the Avalon or Burin peninsulas although scattered ornamental trees were infested in some areas of St. John's. This infestation was probably introduced to the city by transplanted trees.

Parasites of the species Campoplex and Apanteles were released in 1974 and 1975 from sites near Mint Brook, Badger and White River Road. Although native parasites were common, there were no recoveries from the two introduced species.

Year	No. of collections	No. of larvae per tree sample		
		Min.	Avg.	Max.
1977 - Island	84	0.3	17.4	130.0

Large Aspen Tortrix, Choristoneura conflictana (Wlk.) and Poplar Leaf Roller, Anacampsis innoculella Zell. — Larval numbers of the tortrix have declined in the past year in central Newfoundland. However, the high numbers and combined feeding with the leaf roller caused moderate to severe damage throughout the Exploits Valley Watershed between Millertown and Botwood. In western Newfoundland light to moderate damage of aspen was recorded from Springdale to Birchy Dam in the Upper Humber Watershed. In Labrador the tortrix was recorded in low numbers for the first time along the Churchill Road near Goose Bay.

IMPORTANT FOREST DISEASES

Broom Rusts of Conifers — Broom rust of balsam fir caused by Melampsorella caryophyllacearum Schroet., and of black spruce, caused by Chrysomyxa arctostaphyli Diet., were common throughout the Island for the past 3 years and their incidence was moderate to severe. In 1977, additional infections were observed as scattered patches on the Avalon, Burin and Bonavista peninsulas, along the Salmonier Line and near Gander and Carmanville. Up to 35% of the trees were infected at some locations, but no tree mortality appeared to be associated with the pathogens.

Witches' Broom of Black Spruce — Witches' broom of black spruce, caused by dwarf mistletoe, Arceuthobium pusillum Peck, continued to be a serious disease problem for the past few years in wet and low-lying areas from Trout Brook to Crabbes River in western Newfoundland. The incidence of the disease in these areas examined this year varied from moderate to high, with the highest percent infection and tree mortality being 85 and 15% respectively. An average of 10 brooms per tree were found, although the maximum number of brooms recorded on a tree were 40. In several cases the infection was very old, the oldest broom observed was 41 years old.

Stem and Branch Cankers of Lombardy Poplar, Dothichiza populea Sacc. & Briard — This accidentally introduced canker continued to be the most important disease in residential areas on the Island. Several new infections were recorded in the Baie Verte, Springdale and St. John's areas. The incidence of infection was about 35% and tree mortality 15%. In the Corner Brook area tree mortality increased to 40% along city streets.

Ink Spot of Trembling Aspen, Ciborinia whetzellii (Seav.) Seaver — A moderate to high incidence of this disease continued in a 5 km area along the Churchill Road near Goose Bay for the third consecutive year. Approximately 80% browning of foliage was recorded throughout the area. The infestation near McIsaacs Brook in western Newfoundland terminated in 1977.

Rust Gall, Gymnosporangium cornutum Arth. ex Kern — Rust galls of mountain ash were severe in some areas of central Newfoundland and on the Burin and Avalon peninsulas in eastern Newfoundland. The incidence of infection near Badger and the Beothuk Provincial Park was low, affecting about 10-20% of the foliage at each location. A very severe infection occurred on about 30 trees at Salmon Cove Sands; approximately 90% of the foliage was affected. Similar infections occurred along the Witless Bay Line in the vicinity of Country Pond.

Winter Drying — This condition was common on the Avalon Peninsula again this year. Reddening of 50% of the foliage of balsam fir was evident in exposed areas between St. Catherines and O'Donnells and on roadside stands near Riverhead. Between 30-50% damage occurred on windswept hillsides and open areas from Dunville to Point Verde and near Freshwater and Placentia. Several species of ornamental trees were also affected in communities in these areas.

Pine plantations on Tilton Barrens on the Avalon Peninsula were also affected. About 50% of Scots pine foliage was damaged in the Windsor Lake area.

Frost Damage — The occurrence of frost damage on balsam fir and black spruce was very common throughout the Island. In eastern Newfoundland a moderate incidence was recorded in balsam fir and black spruce regeneration along the Trans Canada Highway right-of-way in the Terra Nova National Park. Approximately 50% of the current growth was affected near Cobbler's Brook and near Sandy Pond junction with the Trans Canada Highway. In central Newfoundland a low to moderate incidence was recorded near Millertown, Exploits Dam and the junction of the Sandy Lake-West Branch roads. A low incidence also occurred on Sitka spruce in the plantation at Bakers Steady on Sandy Brook. In western Newfoundland an estimated 25% of the current growth was killed in a 0.5 ha area of balsam fir regeneration near McIsaacs Brook. Light damage also occurred along the Bonne Bay Road and in the Pinchgut Lake-Gull Pond Road areas.

TREE PEST EXTENSION SERVICE REPORT, 1977

Monitoring the insects and diseases of ornamental trees and shrubs in urban centres of Newfoundland and recommending appropriate control measures are the prinicpal functions of the tree pest extension service. During 1977 numerous requests were received by the Newfoundland Forest Research Centre concerning tree and shrub selection, planting and maintenance and pest control.

In 1977 the spruce budworm outbreak spread to the eastern Avalon Peninsula and in July when defoliation became visible, the demand for information pertaining to the control of this insect increased considerably. The general public was informed of the control measures necessary to protect valuable ornamental greenery through the distribution of pamphlets, via the media and by telephone answering service. A television program was also produced which emphasized the necessity of early detection and correct identification if recommended control measures are to be effective. Appropriate precautions to be taken when applying insecticides were also described.

Cooperation from the Forestry Branch, Newfoundland Department of Forestry and Agriculture, was again received and liaison was maintained with the Corner Brook, Gander, and St. John's Regional Offices. Many insect and disease samples were received on a Regional and Unit basis with assistance provided when necessary by personnel from these offices.

A spruce budworm egg-mass survey was again carried out in private and municipal parks throughout the Province. An analysis of these samples showed a decrease in population levels from the 1976 conditions in parks located in western Newfoundland. Other additional services provided were as follows; softwood seedlings and technical services were provided to the town of St. Lawrence (establishment of a tree planting program), and to Castle Hill Historic Site, Placentia (program to reforest barren areas). Advice and laboratory services were also provided to the Department of Transportation and Communications regarding problems experienced when applying the herbicide Tordon.

The major insect pests recorded during 1977 are as follows:

The Spruce Budworm, Choristoneura fumiferana (Clem.) — The present outbreak of spruce budworm that is ravaging the major forested areas of the Province also caused extensive foliar damage to ornamental softwood shade trees. Defoliation was moderate in Corner Brook and Grand Falls, and severe in Gander, Clarenville, Mount Pearl and St. John's.

The Satin Moth, Stilpnotia salicis (Linn.) — This insect continued to cause severe defoliation of ornamental poplars during 1977. Corner Brook and Stephenville experienced severe defoliation (75%-100%), and in Grand Falls, Clarenville, and St. John's it ranged from light to moderate (35%-65%). Some twig mortality was also recorded in several areas.

Birch Casebearer, Coleophora fuscedinella (Zell.) — Defoliation by the birch casebearer is now being experienced throughout most of the Province. Damage was recorded in all urban centres from Stephenville to St. John's. In central Newfoundland, (Grand Falls and Gander), severe defoliation was observed with 100% of the foliage destroyed in many instances.

White Pine Needleminer, Ocnerostoma strobivora Free. — This needle mining insect was first detected in the St. John's area in 1975. It has since spread to Rural St. John's, Mount Pearl, and west to Holyrood. Defoliation has been mainly observed on Jack & Scots pine and classified as light to moderate.

European Pine Sawfly, Neodiprion sertifier (Geoff.) — This sawfly an accidentally introduced pest of a wide variety of native and exotic pines continues to defoliate many of these ornamental trees in urban St. John's. Population levels for this insect appear to be on the increase with numerous localized pockets detected throughout this area. Defoliation ranged from light (10%-15%) to severe (70%-80%).

OTHER NOTEWORTHY INSECTS

Insect	Host(s)	Sample locality	Remarks
Acleris variana (Fern.) Blackheaded budworm	Black spruce White spruce Balsam fir	St. Phillips Paddy's Pond Mount Pearl St. John's	Localized pockets of moderate defoliation

Ocnerostoma strobivora Free. White pine needleminer	Jack pine Scots pine	St. John's Foxtrap Seal Cove, C.B.	Defoliation - moderate
Orgyia antiqua (L.) Rusty tussock moth	Trembling aspen	St. Phillip's	Light defoliation
Pissodes sp. A weevil	Austrian pine	Mount Pearl	Some mortality observed

Cont'd ...

OTHER NOTEWORTHY INSECTS - Concluded

Insect	Host(s)	Sample locality	Remarks
Pristiphora geniculata (Htg.) Mountain ash sawfly	Showy mountain ash American mountain ash	St. John's Gander Corner Brook	Commonly found throughout Newfoundland. Defoliation - light.
Swammerdamia sp. Ermine moth	Hawthorne Cherry spp.	St. John's	Defoliation - moderate
Tipula paludosa Meigen European crane fly	Grasses	St. John's	Moderate damage caused to lawns throughout St. John's area.

APPENDIX I. Results of spruce budworm egg mass sampling 1977.

Plot	location	No. of branches sampled	Cumulative no. egg masses per 10 m^2 foliage	Defoliation* in 1977	Defoliation* forecast for 1978
